## Joyce Miblack Memorial Conference

# Early signs of migration to myelofibrosis

Susan J. Leclair, Ph.D., CLS(NCA)
Chancellor Professor Emerita
University of Massachusetts

## Most of you already know but

Laboratory tests reflect a single moment in time

Includes that day's physical and emotional stress, diet, fatigue level, type and timing of medication, time of day, and so on.

## Most of you already know this as well but

Good laboratory tests are accurate about 95-98% of the time.

Good laboratory tests have a small range of precision, that is, repeated tests on the same specimen will not always give the exact same result.

The tighter the range the more precise the result - but that does not increase accuracy and vice versa.

For most tests, you have to accept the ranges and compare the CHANGE over time.

A general rule is that there are 10,000,000,000,000,000 cells in a liter of bone marrow.

Most adults have 2 liters of bone marrow space.

All change starts with 1 cell going awry.

In the bone marrow, think that every cell undergoes mitosis every 24 hours.

So if you do the math -

A general assumption is that it takes about 5 years for that one odd cell to get to enough numbers to show up and cause trouble.

## Just a sense of work and time

Cells to fill marrow
Cells at diagnosis (5&5)
Cells at clinical remission
Cells at UMRD
Cells to go bad

This takes more time that people believe.

# To make this math a little more interesting

- \* Malignant cells are damaged so not all of them will be able to achieve the same level of mitotic frequency or life span of the normal cell.
- \* It probably takes longer than what the math would support from the time of the 1 cell to full blown signs and symptoms.

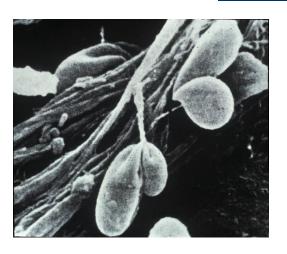

- Mow do you know if progression is happening?
  - \* Not easily
  - Even daily bone marrow examinations will not be able to pick up the small daily changes
  - \* Just as recovery from surgery or trauma shows you, comparison of progression over weeks or months is better.
  - This is NOT a standard light switch (on/off) but much more like a dimmer switch.

# Mow do you know if progression is happening?

#### \* Red cell changes

- ♦ RDW is one possibility
  - Ø It is the most sensitive of all CBC tests
  - It starts to increase weeks before any other result changes beyond the usual daily changes.
- ♦ Shape changes
  - Ø From ET⇒MP
  - As fibrotic material increases in the marrow, the red cells cannot just leave the arrow through the "correct door". They have to slither out through smaller openings and they can get caught..

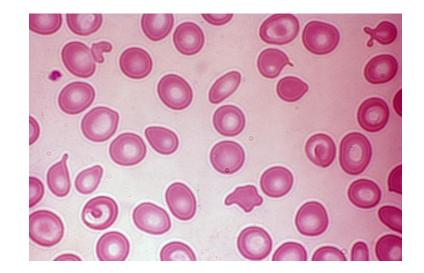

Small and large = anisocytosis

Teardrop and spherocytes = poikilocytosis

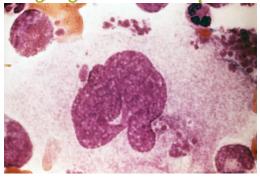

## Liver Function tests that reflect RBC changes

- \* Decreased Haptoglobin -measures increased red cell death well
- Increased bilirubin measures a break down product of red cell metabolism
- - ♦ |soenzymes | and ||
- Elevated Plasma Hemoglobin (usually not done anymore)

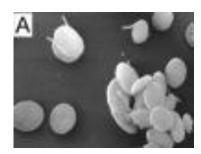

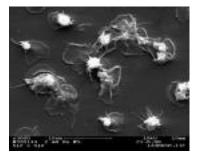

### **Platelets**

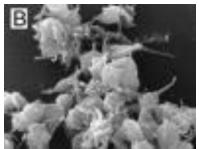

\* Megakaryocytes buds off platelets

× Platelets typically have granules in the center with wispy cytoplasm

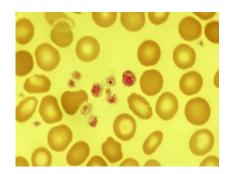

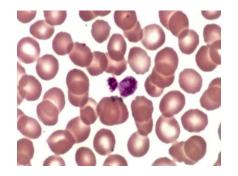

#### R Platelets under bone marrow stress

\* Are bigger and less well organized and have wonky function

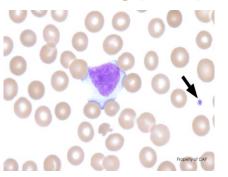

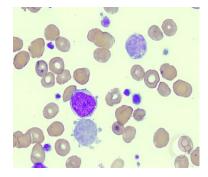

Overtime they get larger, less granular (and less functional)

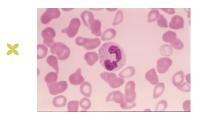

### Granulocytes under bone marrow stress

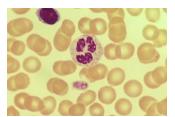

- The faster a cell tries to become mature, the less functional it will be.
- \* Normal
  - During maturation, early granules contain a bleach-like substance.
     They start out dark blue/purple and "bleach" themselves to a lighter blue/lilac. These can kill living organisms.
  - Secondary and tertiary granules degrade, detoxify and make compounds ready for excretion.
- ★ Stress (for any reason)
  - ♦ Granules are darker and bigger
- EDUCATION FOUNDATION
- ♦ Nucleus is less mature
- function is lost

## × Poly's, PMN, Neu, Seg's - fully functional

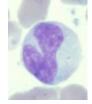

- Spend all of their time in the bloodstream or tissues.
- Can move to a specific site, phagocytize, kill and degrade what it eats
- ♦ Loses granules as it works
- ♦ When there are no more granules, it dies.

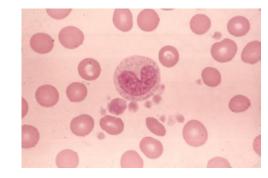

Bands, Non seg's - approximately 80% functional (think teenagers - they can drive)

- ney can drive)
- Spend 50% of their time marginating
- the blood vessel walls (think male teenagers at their dance
- They are clumsy and a little slow but they are functional.

## Granulocytes under bone marrow stress

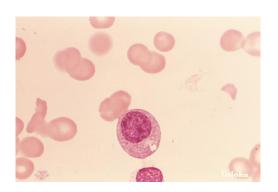

- Metamyelocyte really shouldn't be in the peripheral blood
  - Not fully functional
  - ♦ They can travel but can not phagocytize.

#### \* Myelocytes

- ◆ Can't eat, kill or degrade
- ♦ (an't move
- ◆ The bone marrow is just desperate to put out something.

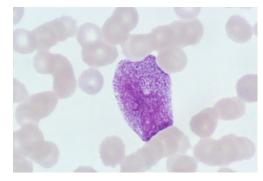

# K Granulocytes under bone marrow stress

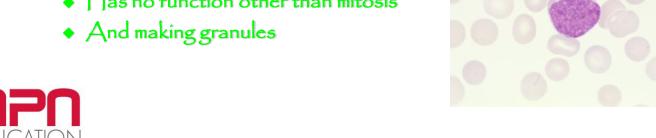

#### \* Promyelocyte

- ♦ Can't move, recognize, eat,
- ♦ No good reason for it to be in the peripheral blood ever

#### Myeloblast (blast)

♦ Has no function other than mitosis

## Granulocytes under bone marrow stress

- \* Every now and again a metamyelocyte can get out of the marrow.
  - ♦ Not consistently
  - Not in increasing numbers
- Every now and again a myelocyte can get out of the marrow
  - ♦ Not consistently
  - Not in increasing numbers

## Granulocytes under bone marrow stress

- Every now and again, a granulocyte can have darker granules but still be functional
  - ♦ Not consistently
  - Not in increasing numbers
- \* Every now and again a granulocyte can be agranular
  - Not consistently
  - Not in increasing numbers

#### What does all this Jibber Jabber mean

Change occurs slowly.

- \* It will be reflected by

  - ◆ The increasing presence of something unusual

    More often than not, more than one anomaly will
    be seen at the same time.
  - None of these require intervention until and unless there is enough to interfere with quality of life
